

Fetch

Browser XHR (XMLHttpRequest) for service calls

- It was horrible
- Many libraries made to help (jquery, axios, etc)

Now we have `fetch()`!

- Native to all modern browsers
- Friendly, promise-based API
- No need for those other libraries

Fetch returns a promise

```
const promise = fetch('/cats');  
promise.then( () => console.log('fetch complete') );
```

The promise resolves with a Response object

- google: MDN Response

```
fetch('/cats')  
  .then( response => console.log(response.status) );
```

Response object does NOT have the parsed body

You need the data from the request body

- Body not yet parsed
- Body may not be fully received yet

Call a method to parse the body

- `.text()` or `.json()` (examples)

These parsing methods **are async**

```
fetch('/cats')  
  .then( response => response.json() )  
  .then( body => console.log(body) );
```

Using the body

```
<ul class="example"></ul>
```

```
const list = document.querySelector('.example');
fetch('/cats')
  .then( response => response.json() )
  .then( cats => {
    const names = people.map(
      name => `<li>${name}</li>`
    ).join('')
    list.innerHTML = names;
  });
```

But: This updates the DOM directly - bad idea!

What is better?

Better design

```
<ul class="example"></ul>
```

```
let names = [];  
  
const listEl = document.querySelector('.example');  
  
fetch('/cats')  
  .then( response => response.json() )  
  .then( cats => {  
    names = cats; // update state  
    render();  
  });  
  
function render() {  
  list.innerHTML = names.map(  
    name => `<li>${name}</li>`  
  ).join('')  
}
```

More improvements to come!

Why better?

state is maintained in variables

- not just in the current DOM
- can rebuild DOM at any time from state
- can consult state without checking DOM
- Keeps state management simple
 - unimpacted by changes to the DOM

We can change state in many places

- always call `render()` or `renderSomeSection()`
 - "render" is my name, but common concept

Handling errors

When service returns an error

- `fetch` promise is **NOT** rejected

Service errors are successful communication

- Only network errors will be caught by `catch()`

Errors by Status code

Some services return *meaningful* HTTP Status codes

- Like REST services (more later)
- May be more detail in the body
 - Body may have its own structure (JSON)

For these we can check for the HTTP status code

- Services with good status codes are important
- `response.ok` is shorthand for status code ranges

This only applies if HTTP status codes are meaningful!

Errors by Content

Some services don't use *meaningful* HTTP Statuses

- Instead send error indicator in the body data

You will have to parse the body then examine it

Fetch Promise rejects if network error

To check for connection error

- catch before parsing response
- but you will likely have to rethrow/reject

```
fetch('/cats')  
  .catch( () => {  
    return Promise.reject( {  
      error: 'network-error'  
    });  
  })  
  .then( response => {  
    // not run in case of network error
```

You decide what your error case looks like

Error Breakdown

```
fetch('/cats')
.catch( () => { // network error caught here
  // rethrow/reject with your own formatted value
})
.then( response => { // Just response status so far!
  if(response.ok) {
    //..
  }
  // If meaningful status
  // - throw/reject with a formatted value
  // - may need to parse error response body
  //   - and throw/reject that
  // If not meaningful status
  // - something went wrong (like 404)
  // - throw/reject with a formatted value
  // - error response body unlikely to help much
})
.then( cats => { // parsed response body
  // Do we need to check it for error indicator
  // - and throw/reject?
```

Error example

```
<ul class="example"></ul>
<div class="status"></div>
```

```
const status = document.querySelector('.status');
fetch('/cats')
  .catch( () => Promise.reject({ error: 'network' }) );
  .then( response => {
    if(response.ok) { return response.json(); }
    // This example service sends JSON error bodies
    return response.json().then(err => Promise.reject(err) );
  })
  .then( cats => {
    const names = cats;
    render();
  })
  .catch( err => status.innerText = err.error );
```

What about network errors?

Reporting Errors to the User

You need to tell the user

- If they need to take action
- Or need to know info is out of date

`console.log()` is NOT telling the user

- Did you look there before this class?

Often DON'T want to show the message from server

- i18n/l12n issues
- Service rarely User-friendly language
- Service may have many clients - can't change

Translating Error Messages

Service may report an error code

- Varies by service author
- Front end code "translates" to user friendly

```
const MESSAGES = {  
  'network-error': "Server unavailable, please try again",  
  'invalid-name': "Name not found, please correct",  
  default: "Something went wrong, please try again",  
};  
// ...  
.catch( error => { // If 'error' is the code  
  const message = MESSAGES[error] || MESSAGES.default;  
  // ...  
}
```

Manually Testing Errors

Easy to test errors where you send bad data

- But how to test server unavailable?

Two options

- Stop server and try front end service call
- DevTools - Network
 - "No throttling" to "Offline"
 - Remember to change back after test!

Error Tips

- Don't leave the user confused
- `console.log()` is **NOT** error handling
- You rarely SHOW the exact service error message

Students lose points on assignments and projects

- Every semester
- Please break the trend

Tell the user what they need to do

- Just like you see on websites

Different HTTP methods

`fetch()` defaults to GET method

It accepts an optional object

- The `method` key allows you to set the method

```
fetch('/cats', {  
  method: 'POST'  
})
```

More HTTP Methods

`fetch()` supports more methods than GET and POST

- DELETE
- PUT
- PATCH
- OPTIONS, TRACE, and HEAD
 - rarely called in `fetch()`

More discussion later

- For now: they are all called by setting `method`

Sending Data

Query params are sent as part of the URL

- the first argument to `fetch()`

Body params can be sent as the `body` option

- Remember: Not with GET
- Body params can be in multiple formats

```
// Not yet complete
fetch('/cats', {
  method: 'POST',
  body: JSON.stringify({ name: 'Maru', age: 12 }),
})
```

Sending Headers

There is a `headers` property

- Adds to/overrides default headers
- Need to tell server what format body is in

```
fetch('/cats', {  
  method: 'POST',  
  headers: {  
    'content-type': 'application/json'  
  },  
  body: JSON.stringify({ name: 'Maru', age: 12 }),  
})
```

Set content-type header when formatted body!

Many servers will not parse the body otherwise

- Confusing error messages about missing data

What about cookies on service call web requests?

Cookies and `Auth` headers

- Controlled by the `credentials` option to `fetch()`
- `omit`, `same-origin` (default), `include`
 - "origin" is protocol+domain+port
 - Compares fetched url to url of current page
- Controls sending cookies
 - And setting received cookies

```
fetch('/cats', {  
  method: 'GET',  
  credentials: 'include',  
})
```

Separating Concerns

So far

- `fetch()`
- `.then()/catch()` chain
- Update state
- Call render

But we have excessive coupling!

- Our call to `fetch()`
- How we use the data
 - Update state
 - Render

Returning the promise

```
function fetchCats() {  
  return fetch('/cats')  
    .catch( () => Promise.reject({ error: 'network' }) );  
    .then( response => {  
      if(response.ok) { return response.json(); }  
      // This example service sends JSON error bodies  
      return response.json().then(err => Promise.reject(err) );  
    });  
}
```

- Makes call
- Converts body/error
- Does NOT alter state or DOM
- Returns the promise

Using the Promise

The **caller** of the function that returns the promise

- Can attach further callbacks
 - To use results
 - Update state
 - `render()`
- Making call and using results
 - Now **decoupled** (concerns separated!)
- That fetching function reusable

Separated fetching concern example

```
fetchCats()
  .then( cats => {
    state.names = cats;
    render();
  })
  .catch( err => {
    state.error = MESSAGES[err.error] || MESSAGES.default;
    render();
  });
```
